## MOD 08 PUZZLE

Based on my research, bias in AI refers to errors in the model's predictions or decisions, like data, algorithms, or human intervention during the development or training. AI bias has major effects on the success and fairness of artificial intelligence which often leads to unfair, biased, or unbalanced results.

In terms of bias, data bias, algorithmic bias, and human bias are defiantly leading the pack. Sampling bias which is a subset of data bias happens when the data used to train does not represent the entire population its meant to serve. Even in the algorithmic bias, if the data is unbiased, the algorithm may present itself as biased.

Human bias can be introduced by humans unintentionally; developers and more can be involved in creating and training the AI. Bias in AI can target you based on your demographic, age, gender and etc. That is a big impact and influence regarding the bias spectrum of AI. False predictions are also connected to the bias of AI.

My biggest concern when it comes to the biases of AI is how it will effect the potential job market in the future. I personally feel a lot of jobs and trades will be lost to AI. The fact that it can complete tasks nearly flawlessly and only requires computational power can make it useful for virtual needs and tasks.
